1

PARTICLE SIZE DISTRIBUTIONS FROM SEVERAL MDI'S WITH A MICROSPACER OR A MICROCHAMBER

A report prepared for Respiratory Delivery Systems, Inc.
Walter J. Makiej, Jr., President

by James D. Blanchard, Ph.D.
Harvard School of Public Health

1. PURPOSE

To determine whether two new spacer devices appreciably alter the mass of respirable particles delivered from several metered dose inhalers (MDI).

2. METHODS

2.1. Tested spacer devices: a Microspacer with a large screen and a Microchamber equipped with the Microspacer, both manufactured by Respiratory Delivery Systems, Inc., Lowell, MA.

2.2. Drugs delivered from MDI's: albuterol, beclomethasone, cromolyn sodium, and flunisolide.

2.3. Aerosol Detection System: Aerosizer (AP8000-1, Malvern Instruments, Inc., Southborough, MA). This instrument measures the time-of-flight of single particles accelerating between two laser beams. Aerodynamic diameter is computed directly from the time-of-flight and the particle density.

The MDI was actuated into a large plenum (a 1.1 L cylindrical inlet leading into a 21.4 L box) which provided volume for the aerosol jet from the MDI to slow without appreciable particle losses as well as time for the Freon to evaporate before the particles are drawn into the Aerosizer. A heater between the plenum and the Aerosizer completely evaporated any residual Freon before sizing. The sampling flow rate was 2 L/min and the aerosol was measured for 10 seconds.

2.4. Protocol:

Immediately before each run, the MDI was actuated into the room to prime the valve and then vigorously shaken. The MDI, with or without spacer, was placed in a rubber gasket at the plenum inlet and then actuated in a consistent fashion. Five seconds after actuation the Aerosizer measurement program was started. In comparison to the MDI alone, the spacer devices tended to slow the aerosol and thus it took longer for these particles to travel through the plenum to the Aerosizer inlet. The five-second delay allowed enough time for the particles to reach the inlet before the measurement started and thus prevented under-sampling of the particle mass from the MDI's with spacers. After the completion of each measurement, the plenum was purged twice with filtered air for 1 minute each time. At the start of the succeeding measurement, the background particle count rate was less than 1% of the measurement count rate.

2.5. Data Analysis:

Aerosol particles from MDI's consist of primary drug particles, which may be coated with nonvolatile additives, and particle agglomerates. The primary particles are commonly balled-milled to a uniform size under $5 \mu\text{m}$; the agglomerates may be any larger size. Since agglomeration is a stochastic phenomenon, agglomerates formed over short time periods have little actuation-to-actuation reproducibility. We defined a respirable particle as being less than $5 \mu\text{m}$ in aerodynamic diameter which encompasses particles that penetrate into the lungs with high efficiency. Larger particles tend to deposit mostly in the mouth, oropharynx, and larynx, especially when traveling at the high velocities associated with an MDI burst. Thus, our determination of whether the spacers had a detrimental effect upon the respirable mass from a MDI was based on characterizing the size distribution of particles less than $5 \mu\text{m}$ in diameter, which essentially consisted of all primary particles.

Particle size distributions are conventionally expressed as a frequency distribution of particle number, volume, or mass as a function of aerodynamic diameter. The number distribution gives the number of primary particles and agglomerates; the mass distribution is most important for calculating respirable dose. However, direct plots of particle mass are not possible with the current Aerosizer software. Since particle mass is equal to particle volume times particle density, we circumvented this problem by assuming drug particle density was always 1.0. To the extent this assumption was accurate, the particle volume distribution equaled the particle mass distribution. Particle mass distributions were parameterized in terms of the respirable aerodynamic mass median diameter ($d_{\text{resp},50}$), which was the particle size with 50% of the respirable mass contained in smaller particles and 50% in larger particles up to $5 \mu\text{m}$, and by the particle size with 95% of the respirable mass within smaller sizes ($d_{\text{resp},95}$). Total respirable mass was computed from the area under the curve of particle volume versus aerodynamic diameter.

3. RESULTS AND DISCUSSION

3.1. Albuterol: Figure 1 compares the total particle number versus aerodynamic size for the MDI actuator alone and with the Microspacer or Microchamber based on a single actuation in each case. It is evident that all the aerosolized albuterol after propellant evaporation consisted of respirable primary particles; there was no evidence of agglomerates. Individual plots and tables for each condition are in Appendix 1. Figure 2 shows that the distributions of respirable particle volume (mass) versus aerodynamic size were similar. The addition of either spacer failed to cause any physiologically meaningful change in $d_{\text{resp},50}$, $d_{\text{resp},95}$ (Table 1), or the total respirable mass (Table 2). Appendices 2 and 3 contain the full data tables for the data shown in Tables 1 and 2.

3.2. Beclomethasone: With beclomethasone there were large numbers of agglomerates in addition to the primary particles (Figure 3). Agglomerates were found with the MDI alone and with the Microspacer, but not with the Microchamber, possibly because this device slowed them sufficiently so that they deposited in this device or the plenum before reaching the Aerosizer inlet. Neither spacer affected $d_{\text{resp},50}$ or $d_{\text{resp},95}$ (Table 1), but there was a 19% decrease in respirable mass with the Microchamber (Figure 4 and Table 2). The 29% increase in respirable mass with the Microspacer could be related to the burst-to-burst variability of the MDI canister used.

3.3. Cromolyn sodium: Cromolyn sodium also formed large numbers of agglomerates; the spacers reduced the agglomerates by about half (Figure 5). The primary particles from the canister alone were unusual in that the distribution had two distinct modes (Figure 6). Neither spacer altered $d_{res,50}$ or $d_{res,95}$ (Table 1), but the Microspacer reduced the respirable mass by 31% and the Microchamber reduced the mass by 20% (Figure 6 and Table 2). Part of this reduction was because each spacer eliminated the second primary particle mode.

3.4. Flunisolide: Flunisolide formed aggregates that the Microchamber was more effective at removing than the Microspacer (Figure 7). As with the other drugs, the spacers had no effect upon the respirable size distribution (Figure 8 and Table 1). Furthermore, the spacers had no appreciable effect upon the respirable mass (Table 2).

4. CONCLUSIONS

These data indicate that the Microspacer and the Microchamber have little or no effect upon the size distribution of respirable particles. With albuterol and flunisolide these spacers also had caused no decrease in the respirable mass. The largest decreases in respirable mass were with cromolyn sodium (up to 31%) and beclomethasone (up to 19%). Since these data are based on single measurements, these changes in respirable mass are more qualitative than quantitative. Nonetheless there is no evidence of pronounced drug loss with either the Microspacer or Microchamber.

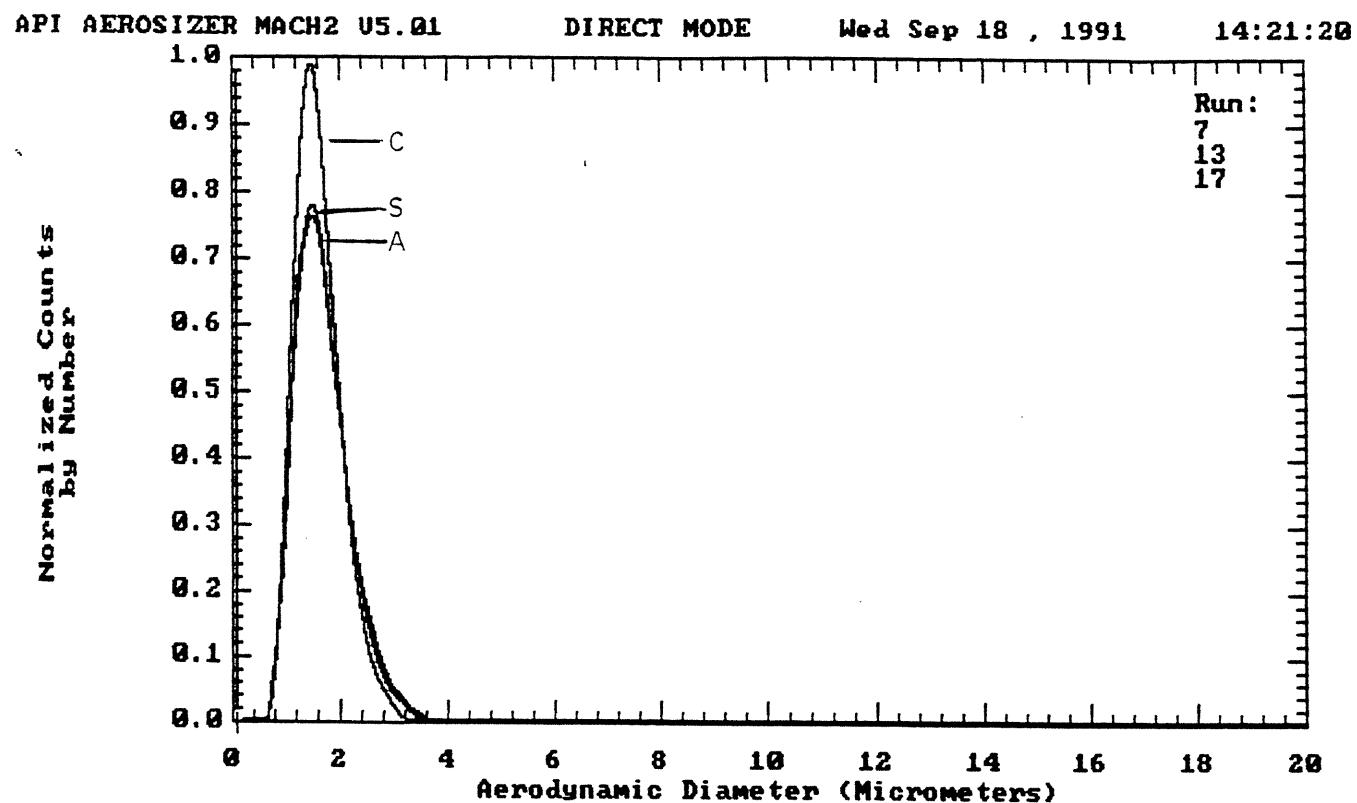

Figure 1. Particle number distribution for albuterol. A = actuator alone, S = Microspacer, C = Microchamber. Plot is normalized relative to the highest count, in this case the Microchamber data.

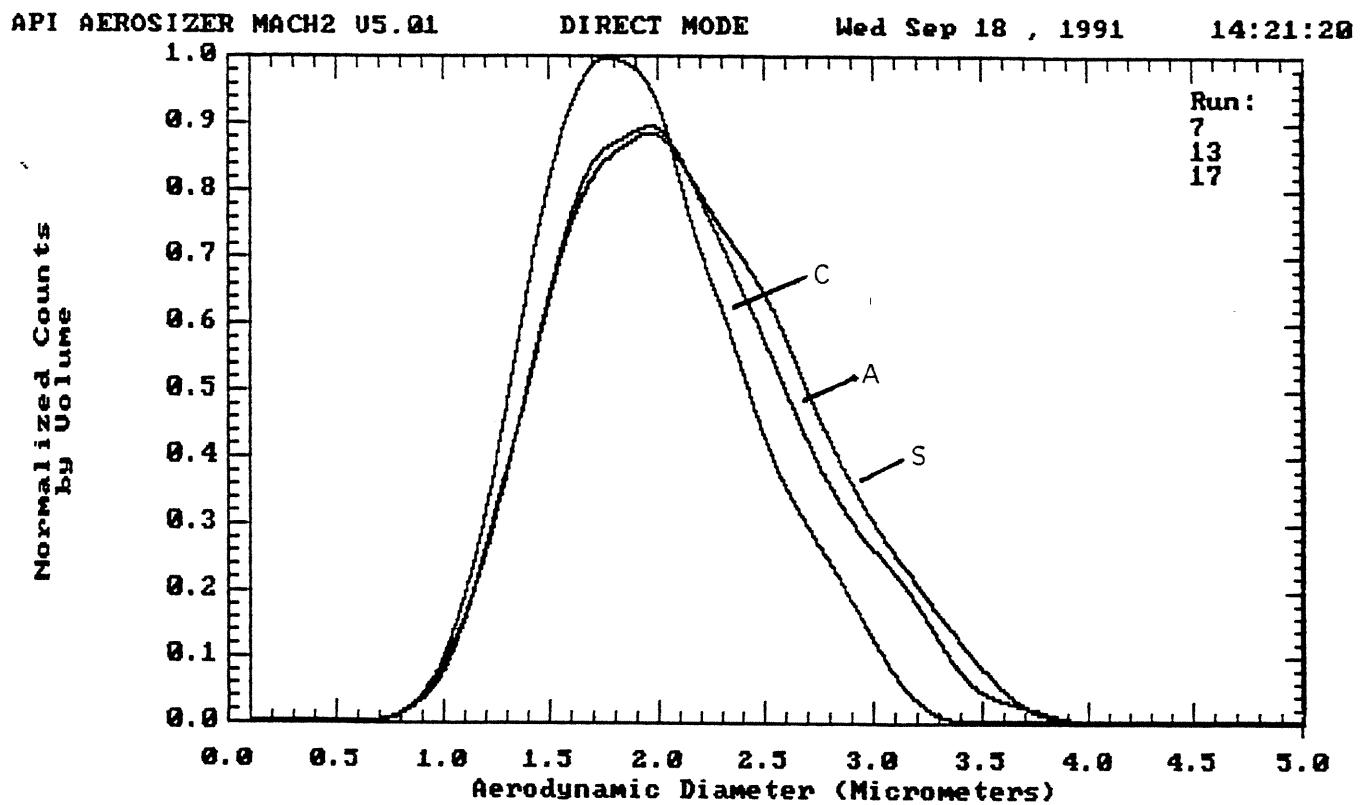

Figure 2. Volume distribution for respirable albuterol particles. This plot also represents the mass distribution when particle density is assumed to be 1.0.

TABLE 1
SIZE DISTRIBUTION FOR RESPIRABLE PARTICLES

		$d_{resp,50}$ (μm)	
	Actuator	Microspacer	Microchamber
	Alone		
Albuterol	2.02	2.05	1.87
Beclomethasone	2.97	2.97	2.80
Cromolyn sodium	2.97	2.81	2.80
Flunisolide	2.78	2.72	2.69
		$d_{resp,95}$ (μm)	
	Actuator	Microspacer	Microchamber
	Alone		
Albuterol	3.01	3.07	2.74
Beclomethasone	3.71	3.69	3.57
Cromolyn sodium	3.86	3.60	3.56
Flunisolide	3.60	3.55	3.51

$d_{resp,50}$ is the particle size with 50% of the respirable mass contained in smaller particles and 50% in larger particles up to 5 μm ; $d_{resp,95}$ is the particle size with 95% of the respirable mass within smaller sizes.

TABLE 2
INFLUENCE OF SPACERS ON RESPIRABLE MASS

Percent Change in Respirable Mass
from Actuator Alone

	Microspacer	Microchamber
Albuterol	+ 2%	+13%
Beclomethasone	+29%	-19%
Cromolyn sodium	- 31%	-20%
Flunisolide	- 4%	+19%

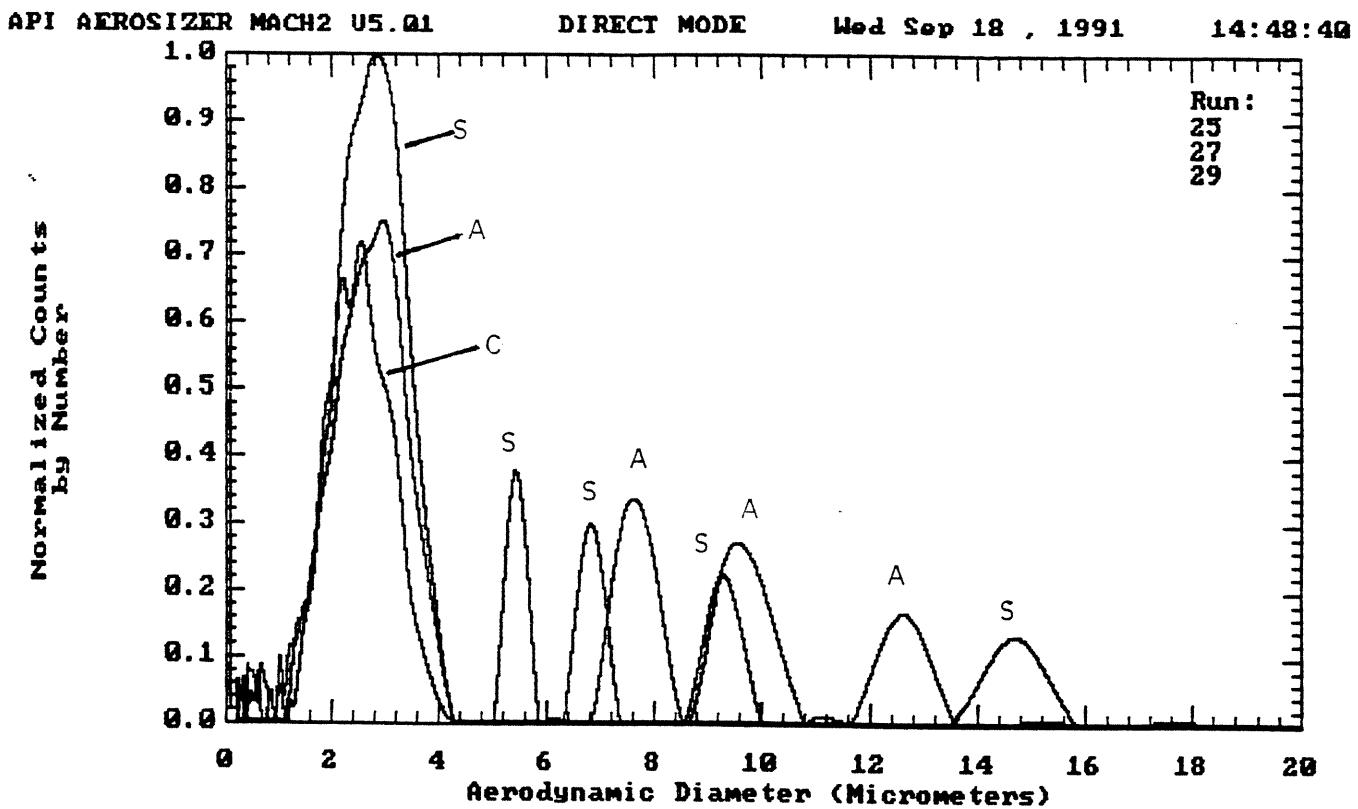

Figure 3. Particle number distribution for beclomethasone. A large number of agglomerates were generated by the actuator that past through the Microspacer, but not the Microchamber.

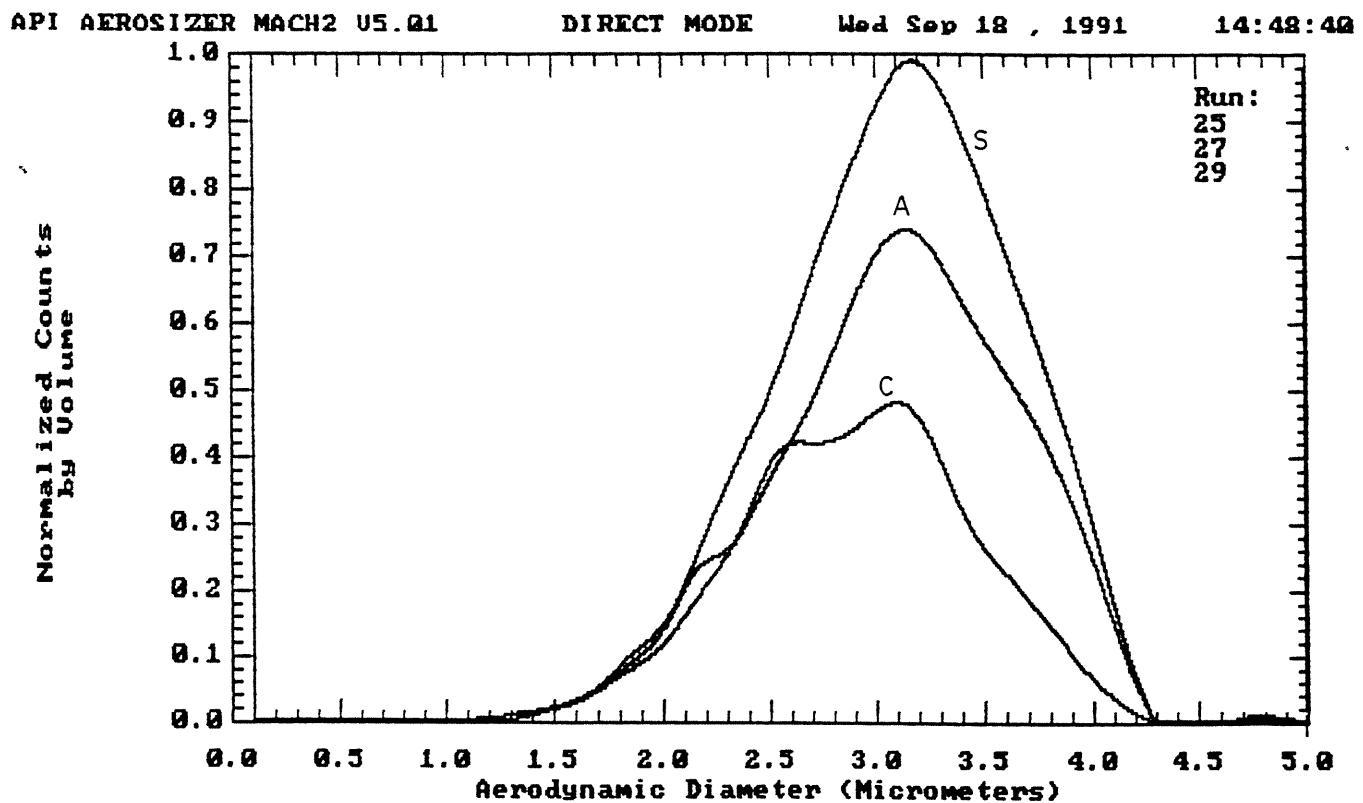

Figure 4. Volume (mass) distribution for respirable beclomethasone particles.

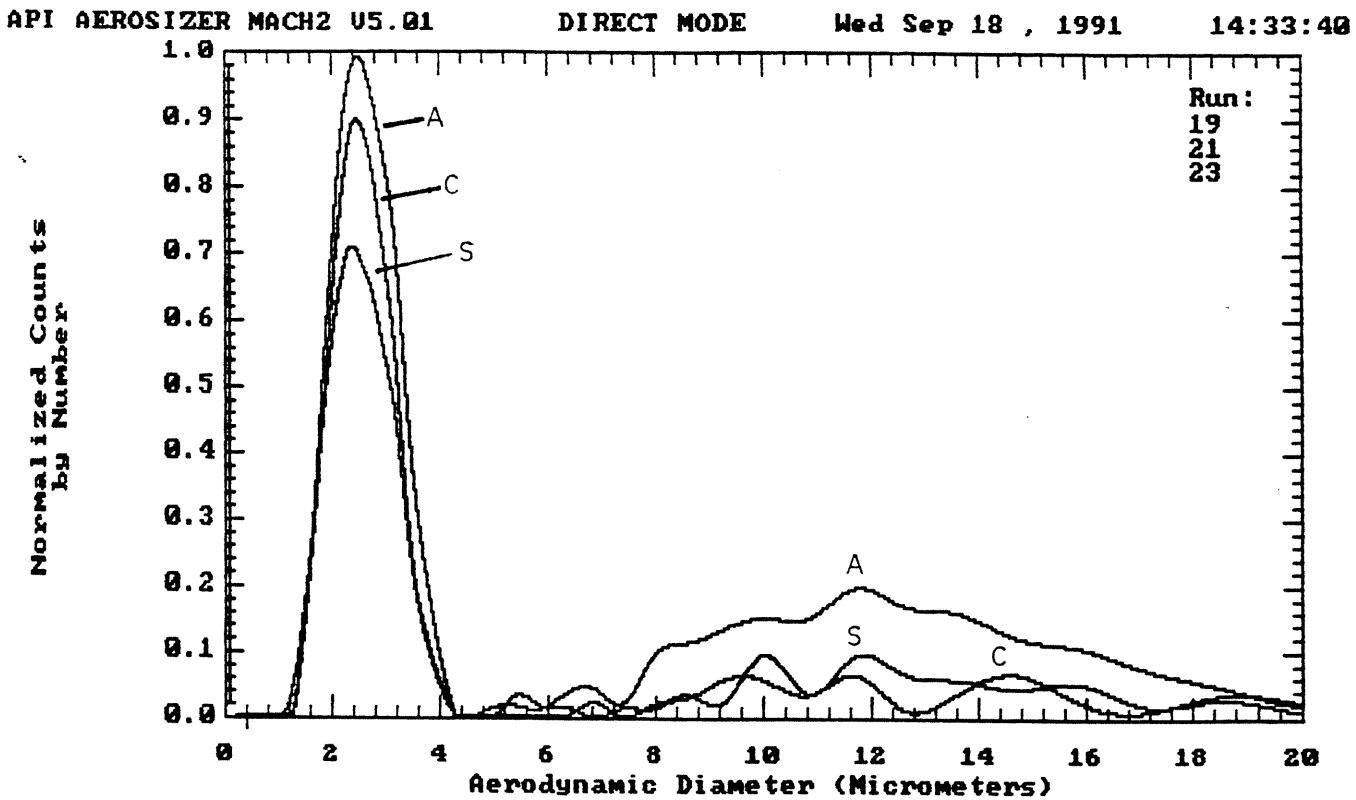

Figure 5. Particle number distribution for cromolyn sodium. The actuator alone produced a large number of agglomerates. The spacers reduced the agglomerate number by about half.

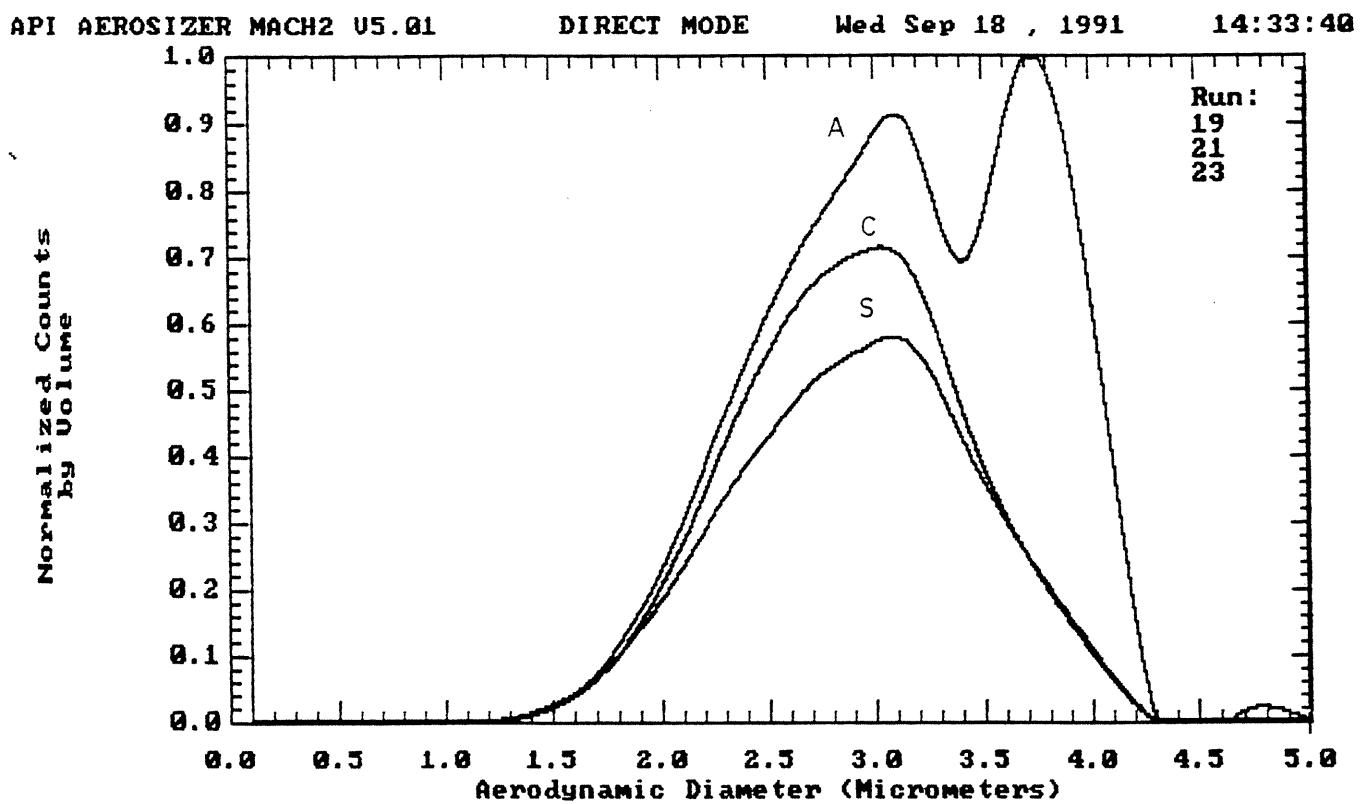

Figure 6. Volume (mass) distribution for respirable cromolyn sodium particles. The actuator produced a pronounced bimodal distribution, but this was eliminated by both spacers.

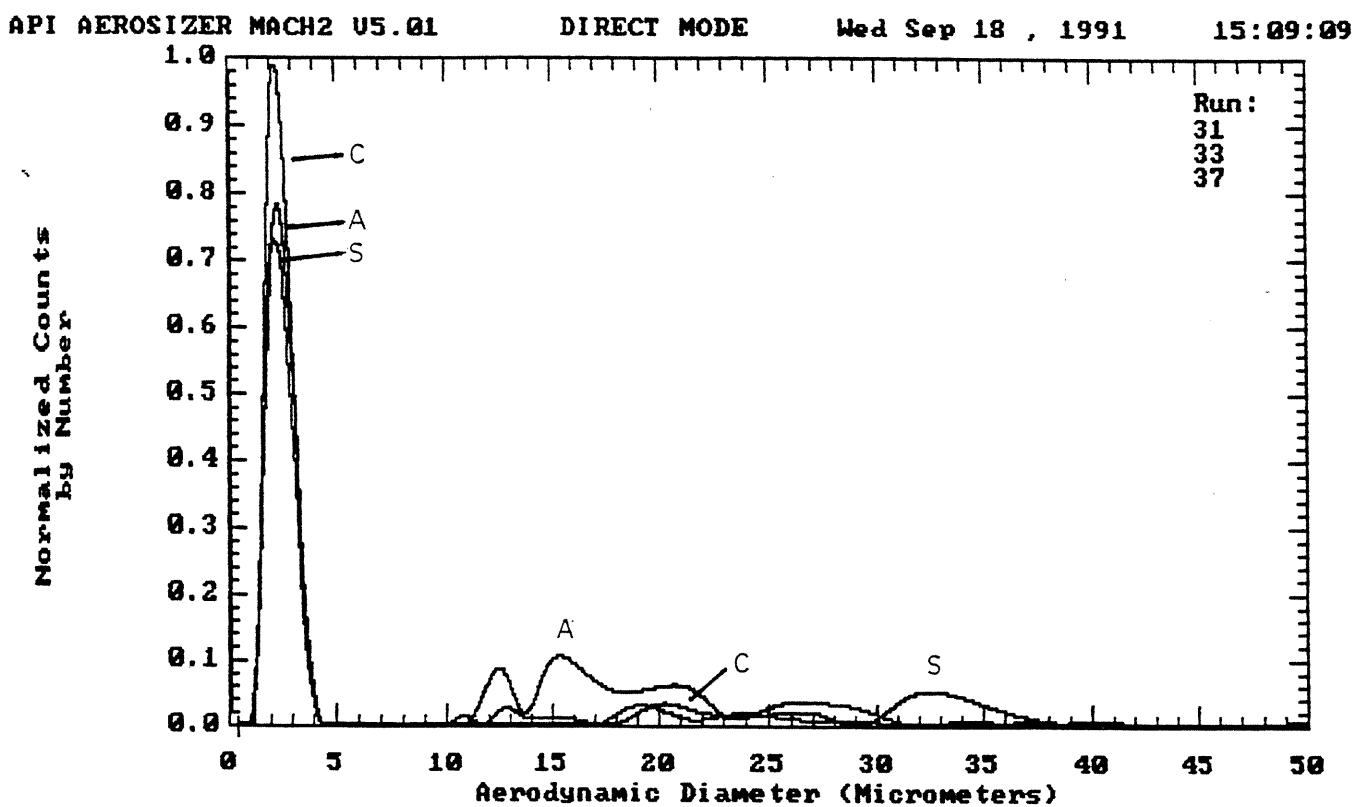

Figure 7. Particle number distribution for flunisolide.

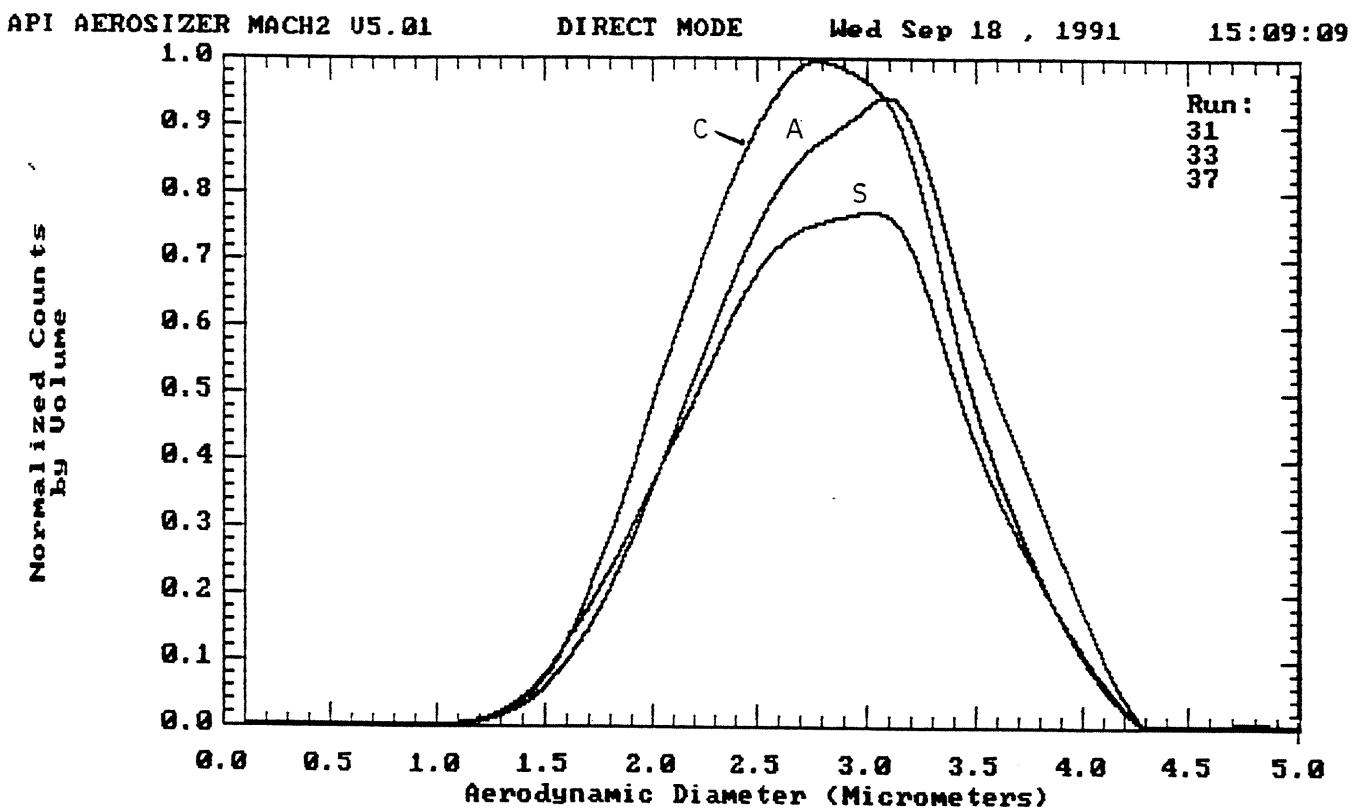

Figure 8. Volume (mass) distribution for respirable flunisolide particles.
